A key characteristic of the CSTR is it is well mixed, meaning the concentration and temperature are uniform over the entire volume

Specifically, CSTRs operate at

the exit concentration & temperature

Hence, the entire volume operates at one single rate, associated w/ the exit conditions

This phenomenon requires perfect mixing; we will show later in the class that this is a large over-simplification that is rarely true in reality

CSTR mole balance:

- In terms of number of moles (N): $V = \frac{F_{A0} - F_A}{-r_A}$. In words, the reactor volume is equal to the amount of species A reacted in the reactor divided by the rate of consumption of species A.
 - If species A is a reactant, $F_{A0} - F_A$ is positive, and $-r_A$ is positive
 - If species A is a product, $F_{A0} - F_A$ is negative, and $-r_A$ is negative
 - If the "amount reacted" is larger, the volume needed is larger
 - If the rate of consumption is larger, the volume needed is smaller

- In terms of conversion (X): $V = \frac{F_{A0} X_A}{-r_A}$
- Same as with batch reactors, if you are solving a reactor design problem for a prototypical CSTR, you can just write down the CSTR mole balance without re-deriving it each time, with the following exceptions.
 - The problem statement asks you to derive the balance.
 - The reactor is not a prototypical CSTR.
- Let's do an example: The gas phase reaction $2A \leftrightarrow B$ exhibits elementary kinetics. It is carried out in a CSTR to 95% of the equilibrium conversion with $P_{A0} = 10$ atm and $T = 400$ K. $K_C = 40$ L/mol, $k_f = 0.1$ L/mol/s, and $v_0 = 1$ L/s. Determine the volume of the CSTR.

Step ① mole balance: $V = \frac{F_{A0} X}{-r_A}$

Step ② rate law: $-r_A = k_f \left(C_A^2 - \frac{C_B}{K_C} \right)$

Step ③ concentration equations: gas phase so

$$C_j = \frac{C_{A0} \left(\theta_j - \frac{v_j}{v_0} X \right)}{1 + \epsilon X} \quad \epsilon = y_{A0} \delta, \quad y_{A0} = 1, \quad \delta = \frac{1-2}{2} = -0.5$$

$$C_A = \frac{C_{A0} (1-X)}{1 - 0.5X} \quad C_{A0} = \frac{P_{A0}}{RT} = 0.304 \frac{\text{mol}}{\text{L}}$$

$$C_B = \frac{1}{2} \frac{C_{A0} X}{1 - 0.5X}$$

Step ① what is X ?

Need $X = 0.95X_e$. Use K_c to get X_e :

$$K_c = 40 = \frac{C_B}{C_A^2} = \frac{\frac{1}{2}C_{A0}X_e}{1-0.5X_e} \frac{(1-0.5X_e)^2}{C_{A0}^2(1-X_e)^2} = 0.86$$

$$0.95(0.86) = 0.82$$

Step ② solve

$$V = \frac{F_{A0}X}{-r_A} = \frac{C_{A0}v_0 X}{K_c \left(C_A^2 - \frac{C_B}{K_c} \right)}$$

Annotations for the equation above:

- $F_{A0}X$: $0.304 \frac{\text{mol}}{\text{L}}$ (pointing to numerator)
- $-r_A$: $0.1 \frac{\text{L}}{\text{mol} \cdot \text{s}}$ (pointing to denominator)
- $C_{A0}v_0 X$: $0.304 \frac{\text{mol}}{\text{L}}$ (pointing to numerator)
- K_c : $40 \frac{\text{L}}{\text{mol}}$ (pointing to denominator)
- $C_A^2 - \frac{C_B}{K_c}$: 0.82 (pointing to denominator)

$$= \frac{\frac{1}{2}C_{A0}X}{1-0.5X} \frac{1}{0.82}$$

Annotations for the simplified equation above:

- $\frac{1}{2}C_{A0}X$: $0.304 \frac{\text{mol}}{\text{L}}$ (pointing to numerator)
- $1-0.5X$: 0.82 (pointing to denominator)
- $\frac{1}{0.82}$: 0.82 (pointing to denominator)

$$0.304 \frac{\text{mol}}{\text{L}} \rightarrow \frac{C_{A0}(1-X)}{1-0.5X} \frac{1}{0.82}$$

Annotations for the final equation above:

- $C_{A0}(1-X)$: $0.304 \frac{\text{mol}}{\text{L}}$ (pointing to numerator)
- $1-0.5X$: 0.82 (pointing to denominator)
- $\frac{1}{0.82}$: 0.82 (pointing to denominator)

$$V = 750 \text{ L}$$
